

SEEing Better Responses

9 Computing Technology

SEE Model

State: Your direct answer to the question. It is usually one clear sentence that gets straight to the main point or idea. This shows the marker you know exactly what the question is asking and you're focused on responding to it.

Explain: Provides more detail about your statement. Here, you show your understanding by elaborating, giving reasons, or outlining processes and effects. The explanation shows you understand not just the facts, but the reasoning, mechanisms, or significance of your initial statement. It's where you clarify 'how' and 'why'.

Example: Illustrates your point in a practical, real-world, or scenario-based way. It shows markers you can apply your knowledge, not just recite definitions. Examples deepen your answer and make it more convincing. They provide evidence that your explanation is relevant and accurate.

Describe

Describe: Provide characteristics and features (NESA Definition)

Describe components of an information system.

An information system is made up of five key components: hardware, software, data, people, and processes.
Hardware refers to the physical devices like computers and servers. Software includes the programs and applications that run on the hardware. Data is the raw facts and figures that are processed. People are the users who interact with the system, including IT staff and end users. Processes are the procedures and rules that govern how data is collected, processed, and distributed within the system. For instance, a school's student management system uses hardware such as computers and servers, software like the student information program, data such as student names and grades, people including teachers and administrators, and processes like enrolment and reporting procedures.

Describe

State: An information system is made up of five key components: hardware, software, data, people, and processes.

Explain: Hardware refers to the physical devices like computers and servers. Software includes the programs and applications that run on the hardware. Data is the raw facts and figures that are processed. People are the users who interact with the system, including IT staff and end users. Processes are the procedures and rules that govern how data is collected, processed, and distributed within the system.

Example: For instance, a school's student management system uses hardware such as computers and servers, software like the student information program, data such as student names and grades, people including teachers and administrators, and processes like enrolment and reporting procedures.

Explain

Explain: Relate cause and effect; Make the relationships between things evident; Provide why and/or how (NESA definition)

Explain the difference between data and information.

Data and information are related but different concepts; data are raw facts, whereas information is processed data that is meaningful. Data consists of unorganised, unprocessed facts such as numbers, dates, and strings without context. Information is data that has been interpreted, organised, or structured to provide meaning and support decision-making. For example, a list of test scores (like 75, 88, 92) is data. When these scores are averaged to show the class average of 85, this result is information because it conveys useful meaning.

Explain

State: Data and information are related but different concepts; data are raw facts, whereas information is processed data that is meaningful.

Explain: Data consists of unorganised, unprocessed facts such as numbers, dates, and strings without context. Information is data that has been interpreted, organised, or structured to provide meaning and support decision-making.

Example: For example, a list of test scores (like 75, 88, 92) is data. When these scores are averaged to show the class average of 85, this result is information because it conveys useful meaning.

Simple Explanation

Element	Meaning	Role in Paragraph	Example Sentence
State	Direct answer	Addresses question clearly	Confidentiality is a fundamental principle in secure software design.
Explain	Clarifies and expands	Shows depth of understanding	Protecting confidentiality prevents unauthorised access and reduces risks such as identity theft.
Example	Concrete illustration	Applies knowledge practically	For example, online banking apps encrypt user data and require secure logins.
